Dear Barry:

We have continued our study of dynamic effects in the spectra of five-membered rings in the solid state. Previously (*J. Am. Chem. Soc.*, **113**, 8958-8960 (1991)) we reported that the  $^{13}\text{C}$  spectrum of solid cyclopentanol decoalesces into at least four sets of resonances per carbon and that of sulfolane into two sets per carbon. We have now examined most of the simple five-membered rings and a few of the analogous six-membered rings. Some of these spectra, including those of cyclopentanone and possibly tetrahydrothiophene 1-oxide, decoalesce at or near the freezing point. Other examples, including cyclopentanol, sulfolane, cyclohexanol, cyclohexanone, and possibly *trans*-1,2-cyclopentanediol, are globular molecules that freeze into a plastic phase that retains some rotational motion. These latter spectra in the solid state closely resemble those in the liquid state, and cross polarization is not needed to obtain the spectra. Below the plastic-to-nonplastic transition, however, these molecules lose their rotational freedom and the spectra exhibit decoalescence. Cross polarization is required, and carbonyl resonances show spinning sidebands.

The slow-exchange spectra of cyclopentanone, 1-methylcyclopentanol, cyclohexanol, and *trans*-1,2-cyclohexanediol contain two peaks of equal intensity for certain carbons. Such an observation may arise either from the presence of equally populated species (conformers, positional isomers, or crystallographic sites, or from a single form with two sites that can exchange to a single averaged site upon the onset of molecular rotation. For the case of cyclopentanone, the latter explanation is excluded, because the carbonyl carbon splits into two, which is possible only when two forms are present.

X-ray structures for these five-membered rings have not been reported, presumably because of the complex phase behavior or the presence of multiple forms in the crystal. Thus it devolves upon NMR to unravel the complex structural situation for these common molecules in the solid state.

Sincerely

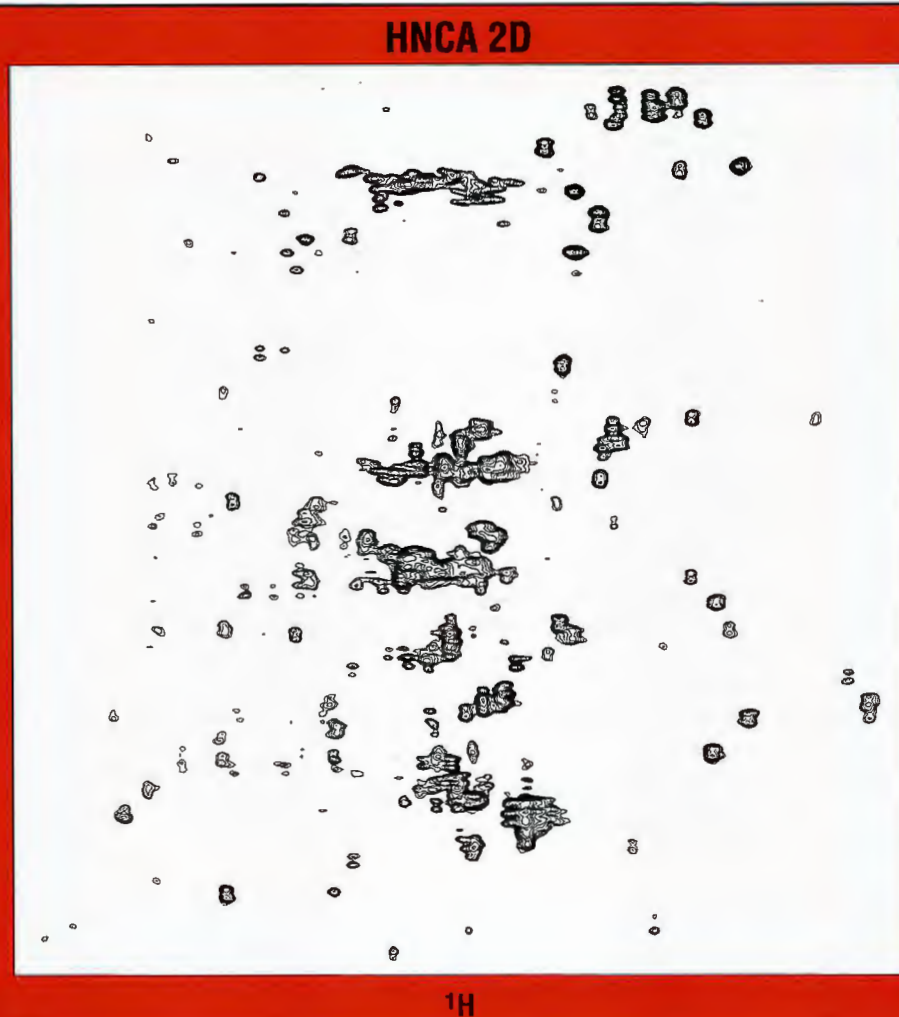

Joseph B. Lambert

Suzanne C. Johnson

# Highest Sensitivity for Biomolecules

*The extraordinary sensitivity in this heteronuclear HNCA spectrum of 300  $\mu$ M <sup>13</sup>C, <sup>15</sup>N-labeled protein (molecular weight 20kD), 120 mM NaCl, 10 mM NaAc in 90% H<sub>2</sub>O/10% D<sub>2</sub>O was obtained with a UNITYplus™ 600 MHz spectrometer equipped with Varian's 10 mm triple resonance probe.*

## 10 mm probes for heteronuclear applications

A remarkable solution for studying biological macromolecules, Varian's 10 mm triple resonance and indirect detection probes are ideal for samples which have limited solubility or are susceptible to aggregation.

These innovative probes deliver exceptional water suppression, short pulse widths, and the highest sensitivity when used with Varian's Ultra•nmr shims™.

They also offer excellent performance and minimization of temperature gradients, even with high-ionic strength solutions.

When combined with Ultra•nmr shims and a UNITYplus NMR spectrometer, 10 mm biomolecular probes open new frontiers in biomolecular research. For details, contact the Varian office near you.

# Varian's 10mm Biomolecular Probes

## Advantages

- Highest sensitivity permits the lowest concentrations to be studied
- Short heteronuclear pulse widths provide efficient decoupling over the full bandwidth of interest
- Excellent lineshape is available with Ultra•nmr shims
- Minimal temperature gradients reduce thermal artifacts
- Salt tolerance permits experiments in solutions of moderate to high ionic strengths

## Applications

- Biological macromolecules which have limited solubility
- Samples that are susceptible to aggregation
- Systems that are available only at low concentrations

Dr. Barry Shapiro, Editor  
 TAMU NMR Newsletter  
 966 Elsinore Court  
 Palo Alto, CA 94303

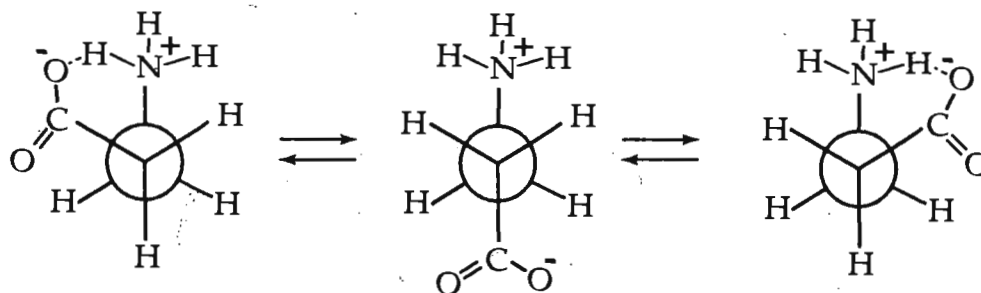

Dear Barry:

For some time now, I have been interested in the presumably worn-out field of application of NMR to conformational analysis of ethane derivatives. It turns out that, not only are there a gaggle of unsolved or unresolved problems, but the field is especially useful for me because of my interest in helping undergraduates get started with research. It works well for undergraduate research because it can be started early on without much knowledge of organic chemistry and the needed NMR can be picked up fairly easily.

Among the interesting paradoxes in this area of research has to do with conformational preferences in water solution. We have just published (Lit, E.S.; Mallon, F.K.; Tsai, H.Y.; Roberts, J.D. *J. Am. Chem. Soc.* **1993**, *115*, 9563-9567, an account of our studies of the changes of conformation of succinic acid with pH (a problem that we pointed out had some interest in a prior TAMU NMR submission, November 1986, #338, p. 12). The gist of the pH effects is that they are not large and not quite what one would expect from conventional wisdom about hydrogen bonds and electrostatic effects. Of course there are nagging uncertainties, because of the necessity to predict what the coupling constants should be for the individual conformations, for example using procedures like those of Haasnoot-Altona, and how close the rotational angles will be to the perfect staggered values. The best we could do indicated that the diacid, the monoanion and the dianion were about 80%, 70% and 43% *gauche*, respectively. As I said, the preferences are not large and one might be surprised that there is not more *gauche* for the monoanion, which conformation could be stabilized by hydrogen bonding.

More disturbing (if you believe in conventional wisdom) even than these results are those reported by Abraham and Hudson, *J. Chem. Soc., Perkin Trans. II* **1986**, 1635-

1640, almost without comment, that the vicinal proton-proton couplings of  $\beta$ -alanine indicate that all three of the possible conformations exist in essentially the distribution expected by statistics of two *gauche* to one *trans*, **independent** of pH! This is especially troublesome for the dipolar ion for which one would expect both a favorable electrostatic, and perhaps hydrogen-bond stabilization as well, for the *gauche* conformation. Because we have measured rather different couplings with succinic acid at high pH than Abraham and Hudson reported, Diana Fort, an excellent summer undergraduate research student from Toronto repeated their experiments with pH on  $\beta$ -alanine and found good agreement.

Because of the rather surprising results with the dipolar ion, Diana also measured the vicinal couplings at 5° and 85° to see if there was a sizable effect that could be ascribed to entropy. However, over an 80° difference in temperature, the change in  $J_{13}$  was only about 0.2 Hz and in  $J_{14}$  only 0.4 Hz, so the effect at best is small. In addition to the examples supplied by Abraham and Hudson, we have looked at several other cases where electrostatic influences and/or hydrogen bonding might be expected to be important. We can only conclude that, while the conventional wisdom may often predict the proper direction that conformational equilibria will take in water solution, the predicted effects will usually be too small by an order of magnitude. The only exceptions are when truly bulky groups are involved, so that steric hindrance is clearly evident.

It would seem that either there must be some compensating balance between steric hindrance arising from solvation, electrostatic attractions and repulsions, entropic influences, solvent structures, hydrogen bondings, and so on, or else these effects must all be small. I wish I knew which.

Best wishes,

Very truly yours

Jack

# AMT Delivers More For Less!

10–90 MHz, 1000 Watt RF power amplifiers for less than \$10,000

## Key Features:

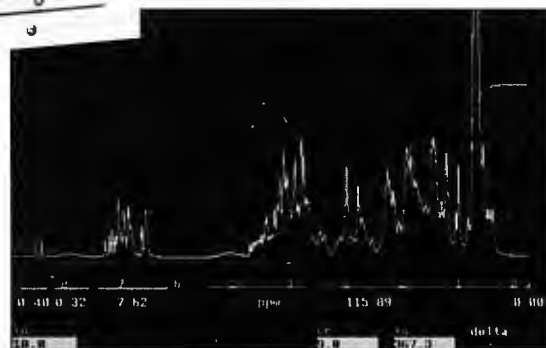

- Full 10–90 MHz frequency range
- 1000 watt power rating
- Linearity  $\pm 1$  dB
- Noise blanking in less than 2  $\mu$ s
- Less than 5% pulse droop
- Dual mode, Pulse/CW operation
- Digital power meter
- Dual range power limits

Model 3426

## The AMT NMR/NMRI product family

SERIES	FREQUENCY	POWER RATINGS
3130	200–500 MHz	50 to 300 W
3200	6–220 MHz	150 to 1000 W
3304	30–310 MHz	400 W
3420	10–90 MHz	1000 to 2000 W

Call Jim Lukes at AMT, or your local distributor NOW  
for a price that will flip your spins!

## Model 3426

10–90 MHz, pulsed,  
solid-state, RF power  
amplifier system

### Electrical specifications:

Frequency range	10–90 MHz
Pulse power (min.) into 50 ohms	1000 W
CW power (max.) into 50 ohms	100 W
Linearity ( $\pm 1$ dB)	0–900 W
Gain (typ.)	65 dB
Gain flatness	$\pm 2$ dB
Input/Output impedance	50 ohms
Input VSWR	$< 2:1$
Pulse width	20 ms
Duty cycle	Up to 10%
Amplitude rise/fall time	250 ns typ.
Amplitude droop	5% to 20 ms typ.
Phase change/output power	$10^\circ$ to rated power, typ.
Phase error overpulse	$4^\circ$ to 20 ms duration, typ.
Noise figure	11 dB typ.
Output noise (blanked)	$< 20$ dB over thermal
Blanking delay	$< 2 \mu\text{s}$ on/off, TTL signal
Protection	1. VSWR: infinite VSWR 2. Input overdrive: up to 10 dB 3. Over duty cycle/pulse width 4. Over temperature

### Supplemental characteristics:

Connectors, rear panel	1. RF input: BNC (F) 2. RF output: Type N (F) 3. Noise blanking: BNC (F) 4. Interface: 25 pin D(F), EMI filtered
Indicators, front panel	1. AC power on 2. Peak power meter 3. Over pulse width 4. Over duty cycle 5. Over temperature 6. Over drive 7. CW mode
System monitors	1. Forward/Reflected RF power 2. Over pulse width/duty cycle 3. DC power supply fault 4. Thermal fault
Front panel controls	1. AC power 2. Pulse width 3. Duty cycle
Cooling	Internal forced air
Operating temperature	$+10$ to $40^\circ\text{C}$
AC line voltage	208/230 VAC, $\pm 10\%$ , 50–60 Hz
AC power requirements	2000 watts
Package	Rack mount
Size (HWD, inches)	$8.75 \times 19 \times 20.25$
Net weight	100 lbs.

Dear Dr. Shapiro,

### Multiple Conformations of Anthopleurin-A in Solution

Anthopleurin-A (AP-A) is a member of a class of sea anemone-derived polypeptides which interact with the voltage-gated sodium channel. In the mammalian heart this results in delayed inactivation of the channel, producing a positive inotropic effect without affecting blood pressure or heart rate.

We have been interested for some time in the elucidating the 3D structure and structure-function relationships of AP-A, and have published a low-resolution structure of AP-A (1) and a higher-resolution structure of the related polypeptide ShI (2). Even in our early studies at 300 MHz, it was clear that AP-A had far too many NMR resonances for a protein of 49 residues. We suggested then that this reflected conformational heterogeneity and that the origin of this was *cis-trans* isomerism of the Gly40-Pro41 peptide bond (3). Although we were subsequently able to confirm that conformational heterogeneity was indeed the cause of the observed peak splitting (4), it proved frustratingly difficult to confirm the role of Pro41 because of peak overlap, even at 500MHz.

With access to an AMX-600 spectrometer, we have now recorded new data on AP-A, which are being used to refine its structure in solution. The new spectra have had two spin-offs, which are the subject of this (much overdue) contribution:

- i) We now have complete assignments for resonances from the major conformer of AP-A and a nearly complete set for the minor. As a result, we are able to confirm that *cis-trans* isomerism of the Gly40-Pro41 peptide bond is indeed the cause of the major peak splitting noted previously. Interestingly, however, the major conformer adopts the *cis* configuration, as indicated by the observation of Gly40 C $\alpha$ H to Pro41 C $\alpha$ H sequential connectivities for the major form and C $\alpha$ H-C $\delta$ H connectivities for the minor, as shown in Figure 1A. A 2D HMQC spectrum of AP-A at natural abundance (Figure 1B) provides further support for this, with the chemical shifts of the Pro41 C $\beta$  resonances in the major and minor conformations being 33.5 and 30.2 ppm, respectively, in close agreement with the values of 33.1 and 30.6 ppm observed in the *cis* and *trans* forms, respectively, of model peptides. The two conformations are in slow exchange at ambient temperatures, but in a NOESY spectrum at 315 K, a chemical exchange cross peak is observed between the major and minor resonances of the well resolved Cys46NH proton.
- ii) In addition to the peak splitting due to Gly40-Pro41 peptide bond isomerism, another form of conformational heterogeneity is also present in the molecule, as reflected in the observation of as many as four distinct resonances for several protons. This is illustrated in Figure 2. The relative intensities of the peaks are approximately 18:9:1:1. As these peaks are present in spectra of both AP-A purified from *Anthopleura xanthogrammica* and synthetic AP-A (5), it is unlikely that they are chemical contaminants. Rather, they appear to reflect additional conformational heterogeneity in the molecule. So having sorted out one source of heterogeneity in AP-A, we now have to identify another! In a wider context, it is likely that the presence of minor conformers of proteins in solution is more common than previously thought, and that high field NMR will identify many other examples.

# INTRODUCING THE QXI™ PROBE SERIES

## QUADRUPLE RESONANCE X-NUCLEUS DECOUPLING INVERSE PROBES

**Bruker introduces a new series of 5 mm quadruple-resonance inverse probes for 4-channel high-field AMX or AVANCE DMX spectrometers.**

These new high performance water suppression probes are aimed specifically at the special requirements of our NMR customers who work with labeled oligonucleotides or with nucleic acids forming complexes with fully-labeled proteins and peptides. This new probe series is called QXI™ and offers proton observation, and simultaneous decoupling of phosphorus, carbon, and nitrogen and of course still provides for a deuterium lock.

Some possible applications include (i)  $^{31}\text{P}$  -  $^{13}\text{C}$  -  $^{15}\text{N}$  magnetization transfers in labeled oligonucleotides, (ii) decoupling of  $^{31}\text{P}$  to avoid sensitivity losses during  $^{13}\text{C}$  -  $^{15}\text{N}$  magnetization transfers in labeled oligonucleotides, or (iii) just a convenient way of measuring both  $^1\text{H}/^{13}\text{C}/^{15}\text{N}$  and  $^1\text{H}/^{13}\text{C}/^{31}\text{P}$  triple-resonance experiments with the same probe.

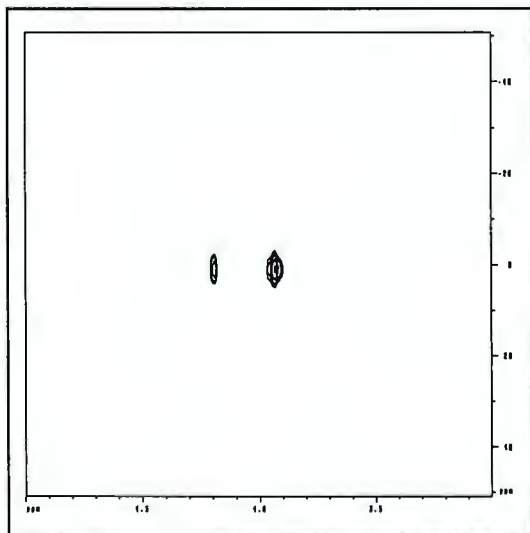

Figure 1: H(C)P correlation of  $^{13}\text{C}$ ,  $^{15}\text{N}$  labeled 5'-GMP. The H(5',5'')-P and H(4')-(C(4'))-P cross peaks are shown.

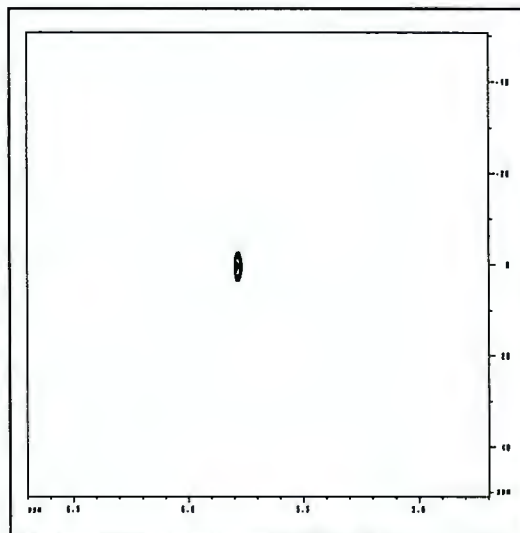

Figure 2: H(C)N correlation of  $^{13}\text{C}$ ,  $^{15}\text{N}$  labeled 5'-GMP. The H(1')-(C(1'))-N(9) cross peak is shown.

NMR

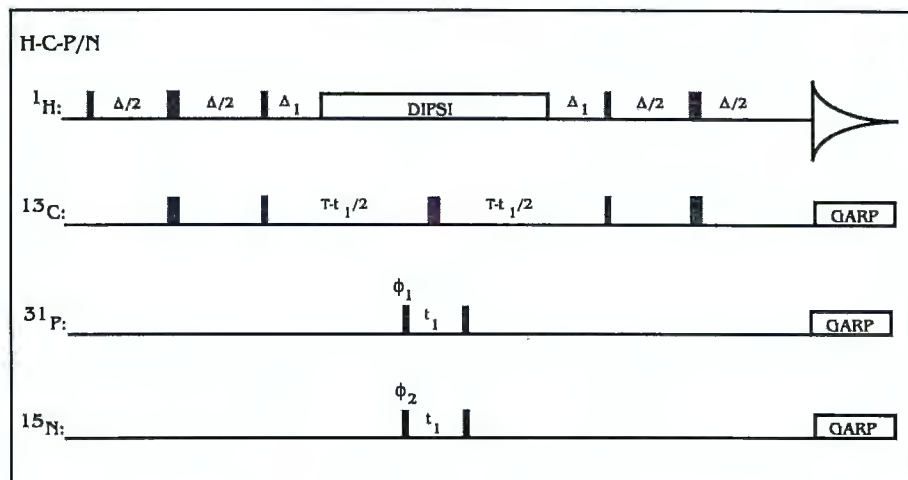

Figure 3: Pulse sequence of a simultaneous H(C)P and H(C)N experiment of  $^{13}\text{C}$ ,  $^{15}\text{N}$  labeled 5'-GMP provided by Prof. G. King, University of New South Wales. The sets of experiments are acquired one with  $\phi_1=0,2$ ;  $\phi_2=0,2$ ;  $\phi_{\text{rec}}=0,2$  and the other with  $\phi_1=0,2$ ;  $\phi_2=2,0$ ;  $\phi_{\text{rec}}=0,2$ . Summation of the two experiments yields the H(C)P correlation, subtraction the H(C)N correlation. Parameters:  $\Delta=3.24$  ms,  $\Delta_1=2.2$  ms,  $T=24$  ms, 256 complex points in  $t_1$  were recorded with 4 scans per increment; 1024 complex points in  $t_2$ . The spectra were recorded with a  $^1\text{H}$ ,  $^{13}\text{C}$ ,  $^{15}\text{N}$ ,  $^{31}\text{P}$  probe on an AMX600 by H.Schwalbe, J.W. Goethe University, Frankfurt.

For a 600 MHz QXI probe we can specify proton sensitivity at  $S/N > 550:1$  for 0.1% EB. The following  $90^\circ$  pulse widths are specified for an AVANCE<sup>TM</sup> DMX600:

$^1\text{H}$	< 10 microsec
$^{31}\text{P}$	< 20 microsec
$^{13}\text{C}$	< 15 microsec
$^{15}\text{N}$	< 45 microsec

This extremely good proton and inverse sensitivity and excellent phosphorus, carbon and nitrogen bandwidths should allow very demanding biological NMR experiments. The resolution, non-spinning and spinning lineshape of the QXI probes are identical in performance to Bruker's 5 mm TXI triple resonance inverse probes, which are in wide use among our customers.

In conclusion, the excellent sensitivity, short pulse widths and good resolution and lineshape of the QXI-series are ideally suited for demanding nucleic acid and other NMR experiments in water. We anticipate that the experiment shown here, will be the first in an entirely new family of NMR experiments geared towards nucleic acids research, which are technically feasible for the first time with the innovative QXI design. For more details please contact your nearest Bruker representative or applications laboratory.

Chemical Division

November 15, 1993

(received 12/6/93)

Dear Dr. Shapiro:

Most of our work involves supporting the process development efforts of the pharmaceutical chemists in the Chemical Division. This means rapidly identifying the exact structure of an impurity as well as providing routine 1D NMR service work. In order to devote more time to identification activities we long ago automated the acquisition and processing of 1D NMR data so that the chemists could acquire spectral data directly. The most labor intensive aspect of acquiring these data is plotting the resulting spectra and, as such, we would like to share with you some of the microprograms written over the years to lessen the burden.

The set of 1D NMR experiments provided to the chemists is one  $^1\text{H}$  spectrum and three  $^{13}\text{C}$  spectra (a fully decoupled (CPD), a DEPT90, and a DEPT135). The  $^{13}\text{C}$  data is most easily interpreted when presented on a single sheet of paper as a stacked plot, as in figure 1. These experiments were acquired on a Bruker AMX instrument using the standard set of automation routines. To plot in this manner go into EDP and set the AUNMP parameter to 'proc\_no' for the first two  $^{13}\text{C}$  experiments (i.e. CPD and D135). Set the third experiment to 'PLOTCPDEPTS', which is a program written in-house to plot the spectra on a single sheet of 11x17 paper. Figure 2 lists the program with the appropriate documentation. 'PLOTCPDEPTS' requires three parameter files, 'HP75CPD', 'HP75D135', and 'HP75D90', which contain only 'plot' and 'outd' information. The contents of the 'plot' files are accessible through EDG and presented in figure 3.

Those of you using the automation routines on Bruker AM systems should use the program listed in figure 4 ('post.au'). This routine differs from Bruker's 'pr4d.au' program in that the acquisition files can be prepared as 'combined standard experiments' instead of as pseudo 2D experiments. Please note that in each of the three  $^{13}\text{C}$  acquisition programs the line 'wr CPD' (or DEPT90 or DEPT135) must be added after the 'wr @' in the appropriate 'X0\_AU' files. These temporary data files are required by the processing routine 'post.au'. (The reason for this escapes us for the moment. It has been two years since we retired our AM systems and our memories are rusty.) As in the above case the first two  $^{13}\text{C}$ 's should not be immediately processed and should use the 'prno.au' processing program modified as in figure 5.

Sincerely yours,

Stephen Grode

## ALUMINA TUBE FOR $^{29}\text{Si}$ AND $^{11}\text{B}$ NMR

Shigemi CO. has recently developed an unique alumina tube for  $^{29}\text{Si}$  and  $^{11}\text{B}$  NMR. The construction of the tube consists of a standard glass NMR tube connected to a highly densified alumina bottom which holds your sample. By using our alumina tube, the  $^{29}\text{Si}$  spectrum is free from a broad  $^{29}\text{Si}$  signal and the spinning sidebands are suppressed to a minimum owing to its precision and quality. As of now, only Shigemi can offer you this very specialized and high quality tube for a reasonable price.

Type	A Length (mm)	B OD (mm)	C ID (mm)	D ID (mm)	Camber ( $\mu$ )
Si-005	180	$4.965 + 0$ $- 0.005$	$4.0 \pm 0.1$	3	$\pm 0.02$
Si-010	190	$10.0 + 0$ $- 0.01$	$9.0 \pm 0.1$	7.8	$\pm 0.02$

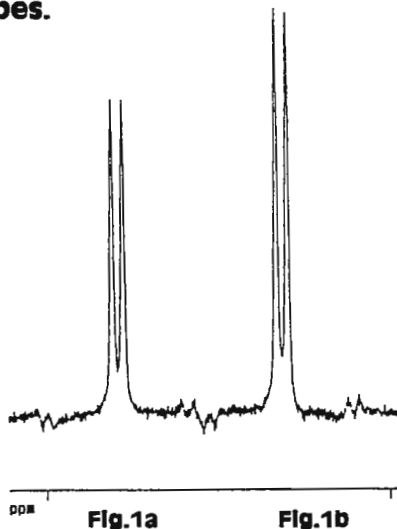

Type	Diameter	Price for 5 tubes
Si-005	5mm	\$300.00
Si-010	10mm	\$400.00

## Specially designed Thin Wall NMR Sample Tube

Shigemi's high precision thin wall NMR sample tube has a unique construction. The wall thickness of this particular tube is reduced only around the position of the detection coil. The result of this new invention allows an increase in the sample volume and higher sensitivity without sacrificing its mechanical strength. Therefore, there is no need for special handling during routine usage of our Shigemi NMR tubes.

The spectra of 20mm sucrose in  $D_2O$  were obtained with a single scan without apodization prior to Fourier transformation on a Bruker AMX-600 spectrometer at 298 K. By using Shigemi high quality 5mm standard tube (Fig.1a) and the Shigemi highly sensitive thin wall 5mm tube (Fig.1b), the spectra confirms a sensitivity enhancement of about 10%.

Department of Physics

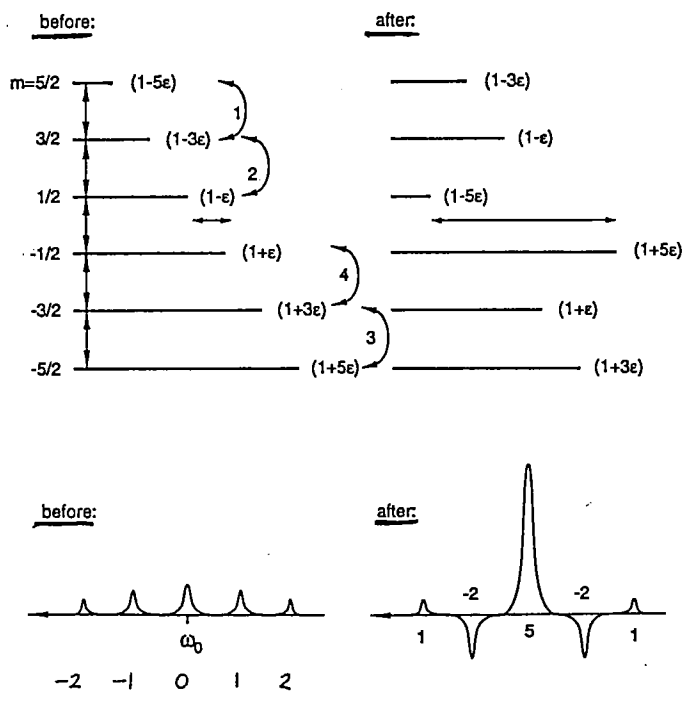

November 29, 1993  
(received 12/6/93)

Dear Dr. Shapiro:

We recently reported a simple scheme for enhancing the sensitivity of central transition NMR of half-integer quadrupolar nuclei (Chem. Phys. Lett. **209**, 287, (1993)). In the present letter we discuss some of the practical aspects of the technique (probe, rf level, and frequency sources).

The basic technique is really pretty simple. The energy levels and NMR spectrum of a spin- $5/2$  is shown in Fig. 1 below, for the case of  $\omega_Q \ll \omega_0$ . There are five resonance transitions (2, 1, 0, -1, -2). The Boltzmann equilibrium populations are shown in Fig. 1, with  $\epsilon = \hbar\omega_0/2kT \ll 1$ . At equilibrium, the population difference of the  $m = \pm 1/2$  levels is  $2\epsilon$ . By *selectively inverting* the satellite transitions in the order 2, 1, -2, -1 (or -2, -1, 2, 1), the population of  $m = 5/2$  is transferred to the  $m = 1/2$  level (and  $-5/2$  to  $-1/2$ ). The resulting populations are shown in Fig. 1. The population difference of the  $m = \pm 1/2$  levels has been increased to  $10\epsilon$ , a  $\times 5$  increase in sensitivity for any subsequent experiment on the central transition.

Figure 1

In powders and glasses the satellite transitions are inhomogeneously broadened and are unresolvable. Thus, inversion by selective  $\pi$  pulses is not possible. But it is easy to invert the satellite transitions by *adiabatic passages*. The frequency of the rf carrier is started above the highest expected satellite and swept down in frequency, ending just above the central transition ( $\sim 50$  kHz above). As shown in Fig. 2, the process is repeated for the low frequency satellites. This procedure automatically inverts the satellites in the order 2, 1, -2, -1. In practice, a sensitivity enhancement of 4.0-4.5 is obtained for spins- $5/2$  ( $^{27}\text{Al}$ ,  $^{17}\text{O}$ ). In general, the ideal enhancement is a factor of  $2I$ . We note that no fussy adjustments are required: the technique simply works.

Experimental requirements: relatively low rf powers are adequate for the sweep. Typically, the sweep may last 5 - 20 ms with  $\gamma H_1/2\pi = 5$  kHz (as measured in solution). We commonly use a 25 watt transmitter with 5 mm samples.

For **frequency sources**, we employ an FM generator. The HP 8640 B is particularly nice, but has a narrow FM range ( $\pm 3\%$ ). The FM range can be increased by running the FM generator at a high frequency (e.g. 400 MHz) and heterodyning it down against a stable source (e.g., a synthesizer). We drive the FM input with a DAC mounted in our spectrometer's control computer. RC filtering makes the frequency vary smoothly, and not step-like. We sometimes use the FM source for the rf sweeping and a synthesizer for inspecting the central transition; this is a nearly ideal arrangement. We switch between the rf sources with a PIN-diode switch (as in Mini-Circuits' catalog).

The **probe** must be broadband (low Q) for the rf sweeps. But detection with a low Q probe would kill the sensitivity! So we use a probe that has both high Q and low Q ports (Fig. 3). The high-Q port is coupled to a tap on L; the tap position is adjusted to give 50  $\Omega$  resistive. The low Q tap, up higher on the coil, is *overcoupled*; thus the transmitter's output impedance broadens the resonance. Moving the tap up (away from ground) further decreases Q. To switch between the low Q and high Q ports we have used a coax relay ( $\sim 50$  ms operating time). The sweep uses low Q; the inspection pulses and detection use high Q. We have also used crossed diodes for switching (Fig. 3), with rf sweep and inspection pulses using low Q and detection using high Q. Both schemes work well. Since the low Q port is never 50  $\Omega$  resistive, it is tuned with an rf sweeper and a pick-up coil.

Though we have not tried it, a crossed-coil circuit should work too. The transmitting coil would be low Q; the inner receiving coil high Q. As shown in Fig. 3, crossed diodes across the receiving coil would help avoid coupling between the circuits. Diodes in the transmitting circuit would shift its frequency during detection, again avoiding coupling. Most glass-package diodes are magnetic; one might try using the junctions of epoxy-cased rf transistors (non-magnetic).

Sincerely,

*Jurgen Haase and Mark Conradi*

# CMX Multi-Channel Applications

The unique channel modularity design of the Chemagnetics™ CMX spectrometer gives you the NMR flexibility you need for solids, liquids and microimaging. The CMX offers the range of capabilities required for today's wide variety of experiments by supporting multiple channels. And the CMX design allows new channels to be added easily and affordably. All this adds up to a "no-compromise" approach to experimental capability.

Chemagnetics utilizes the latest technology to put multi-channel flexibility in the hands of the spectroscopist. Dual 16 bit, 1 MHz digitizers offer maximum dynamic range over the widest bandwidths. And each RF channel in the CMX is equipped with its own pulse programmer, so experiments are never limited by pulse programmer capacity.

The CMX is designed to start small *and* grow, providing the whole spectrum of NMR capabilities as they evolve, when you need them. Multi-channel capability with the CMX - flexibility for tomorrow, available today from Chemagnetics.

## Variable Amplitude Cross Polarization - The Latest Technique from Chemagnetics

The introduction of the Variable Amplitude Cross Polarization (VACP) technique by Professor Steve Smith at Yale University at the 1993 ENC may completely change the approach to optimization of solid state NMR experiments. This technique produces high quality solid state CP/MAS data, even on samples where the match condition may be impossible to optimize, such as weakly coupled systems. This opens up great potential for effective quantitation and comparison of data from different samples.

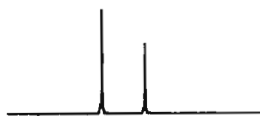

The results shown below obtained at Chemagnetics combine the unique design of the high-speed CMX linear amplitude modulator, amplifier technology, and the ease-of-use, high-speed double resonance Pencil™ spinning probe to demonstrate the power of this technique.

This power to implement new and future techniques lies at your fingertips when you invest in the CMX design philosophy. While others attempt to emulate its flexibility and modularity, the CMX continues to evolve into the most effective, versatile NMR spectrometer available.

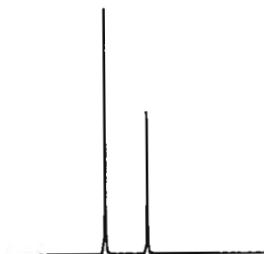

Call to find out more about state of the art performance with the Chemagnetics CMX, the revolutionary and evolutionary NMR system.

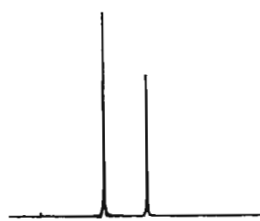

Variable amplitude cross polarization (VACP)  
under -2.6 KHz mismatch condition

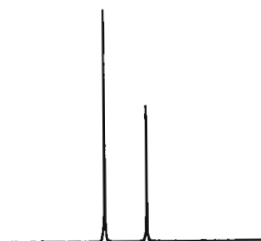

Deliberate "mismatch" of -1.9 KHz

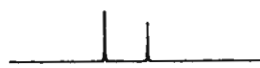

VACP under normal match condition

Normal "ideal" matched conditions

VACP under +2.0 KHz mismatch condition

### **Solid State NMR of the Equine Hoof Wall**

Dr. Shapiro:

The equine hoof wall has been characterized by  $^{13}\text{C}$  solid state nuclear magnetic resonance. The structure and dynamics of the predominant protein component of the equine hoof wall, the intermediate filament keratin  $\alpha$ -helix, were probed. Assessment of these parameters is preliminary to the determination of diffusion rates of solutions and fluorocarbon emulsions containing oxygen directly through the hoof wall to the underlying tissue.

Magic-angle sample spinning with high power proton decoupling and cross-polarization techniques provided spectra from which component carbon resonances of amino acids could be discerned. The hoof is composed of primarily four anatomical regions easily resolved by visual inspection. CPMAS  $^{13}\text{C}$  NMR spectra of ground and dried (~10-50% water loss) material from three regions of different horses (A-C) show nearly identical chemical shifts suggesting the component keratin  $\alpha$ -helices between regions and between horses are structurally similar. Resonances (D) of an unground and undried (native) sample from a different region of the hoof are broadened by ~150 Hz over the dried and ground samples from that same region. Another native sample analyzed with the same spectroscopic parameters revealed an aliphatic region (E) more clearly resolved than in other spectra of ground and dried samples. Major resonances in the native samples (D,E) also show a hydration-induced downfield shift of ~3 ppm.

The equine hoof wall has a definite macroscopic and microscopic orientation. This orientation is due to the horn tubules which run longitudinally from the top to the bottom of the hoof wall. The presence of any preferential molecular-level ordering of the abundant composite keratin filaments with the horn tubules was assessed with static  $^{13}\text{C}$  solid state NMR. The carbonyl powder patterns from ~80-250 ppm of the static spectra (F,G) of samples with tubule preferential order axis parallel (F) and perpendicular (G) to the magnetic field exhibit features of a general chemical shift tensor with no observable orientation effects. A preferential orientation of the keratin fibers to the longitudinal axis of the horn tubules would reveal two different patterns, resulting from carbonyl chemical shift tensors oriented colinearly and at 90° to the applied magnetic field. The similarity in the static spectra do not suggest a bulk

preferential orientation but support the view that the hoof is an interpenetrating fibrous polymer network with keratin arranged co- and abaxially to the horn tubules.

Spin-lattice relaxation times of predominant carbonyl and aliphatic carbons were evaluated. The aliphatic resonances show an order of magnitude increase in relaxation rate over the carbonyl resonances which is not unexpected since the carbonyls residing in the helices have less conformational mobility than aliphatic side chains extending into the interhelical space.

Ultimately, we wish to demonstrate the feasibility of delivering oxygenated emulsions through the hoof wall to supporting tissue rendered ischemic, or oxygen-starved by the disease laminitis. We have shown that solid state NMR is a useful technique for the characterization of the structure and dynamics of component polymeric proteins of the equine hoof wall.

Sincerely,

Matthew C. Szap

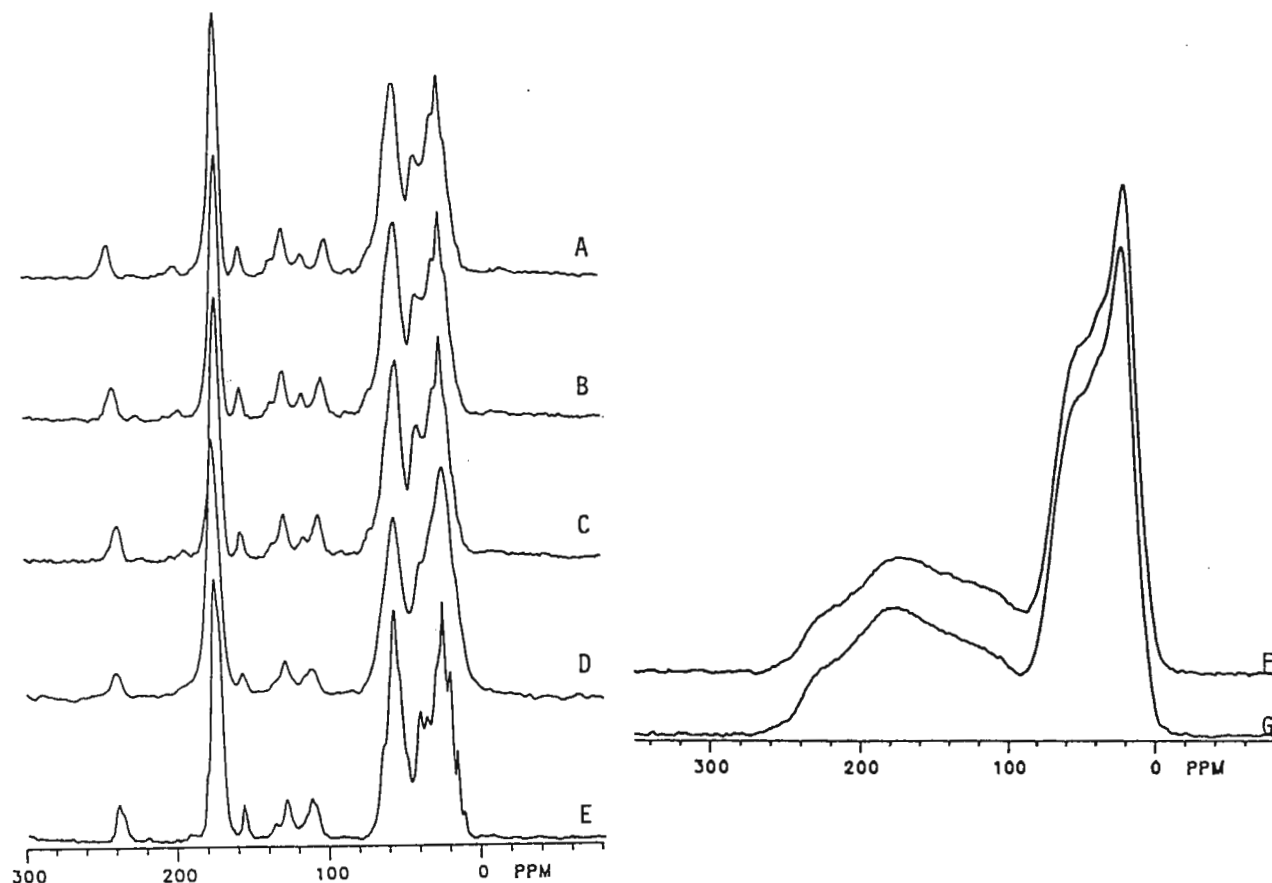

Natalie Foster

This R-1500 FT-NMR spectrum of crotonaldehyde represents a 16 pulse acquisition; each pulse was 10  $\mu$ sec with a pulse interval of 5 seconds.

## HIGH RESOLUTION DIGITAL 60 MHz NMR. GET THE WHOLE STORY IN FIVE SECONDS.

Digital is the new wave in high-resolution 60 MHz NMR spectroscopy. That's because it's not only faster than old analog technology, but it extends the application beyond the acquisition of a simple spectrum. And only Hitachi has it.

Hitachi's R-1500 60 MHz FT-NMR acquires a full spectrum in five seconds. But speed is just part of the story.

The R-1500 will also perform FT experiments, such as solvent suppression,  $T_1$  relaxation time measurement, and Gated Decoupling. And you can manipulate FID data by applying various apodization functions. The result: substantial increases in sensitivity and enhanced resolution.

For a simpler approach to digital 60 MHz NMR, Hitachi offers the R-1200 Rapid Scan NMR spectrometer. It can acquire a quality, high-resolution spectrum in only 10 seconds. The R-1200 is also remarkably sensitive, accumulating up to 256 scans for enhanced signal-to-noise.

Both systems come with a permanent magnet and our exclusive five-year warranty to ensure near-zero maintenance. Over time, the cost of ownership is among the lowest in the industry.

Faster speed, increased sensitivity and better resolution. Only in digital spectroscopy and only from Hitachi, the world leader in 60 MHz NMR, with the industry's best nationwide sales, service and applications support network. For the rest of the story, call 800-548-9001.

December 2, 1993  
(received 12/6/93)Dr. Bernard L. Shapiro  
TAMU NMR Newsletter  
966 Elsinore Court  
Palo Alto, CA 94303Re: **NMR Imaging of Solvent Transport in Macromolecular Systems**

Dear Barry:

The phenomenon of solvent transport into polymers has fascinated researchers for decades. Early on, optical microscopy revealed that systems in which a change in state accompanies solvent transport exhibit a sharp solvent front that penetrates the sample like a shock wave; such behavior has been referred to as case II transport to distinguish it from Fickian transport. The search for a theoretical basis for this type of non-Fickian behavior has been irresistible for both experimentalists and theorists; to date numerous theories abound.

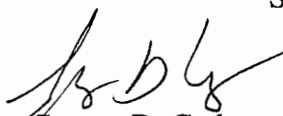

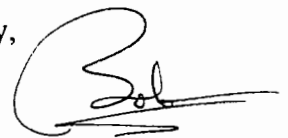

Recently, we have gained considerable insight into the character of solvent transport in polymers and coal through time-resolved NMR imaging of concentration gradients during solvent uptake. Spin-echo 2-D images were obtained on 2 x 2 x 1 mm specimens in reasonable times. In order to ensure that the transport process was also two-dimensional, the upper and lower sample surfaces were protected from solvent infiltration by glass coverslip which restricted the flow of solvent to cross only the exposed faces of the sample. The experimental protocol involved immersing the sample in the solvent for a period of time, removing it from solvent, acquiring an image, and re-immersing it.

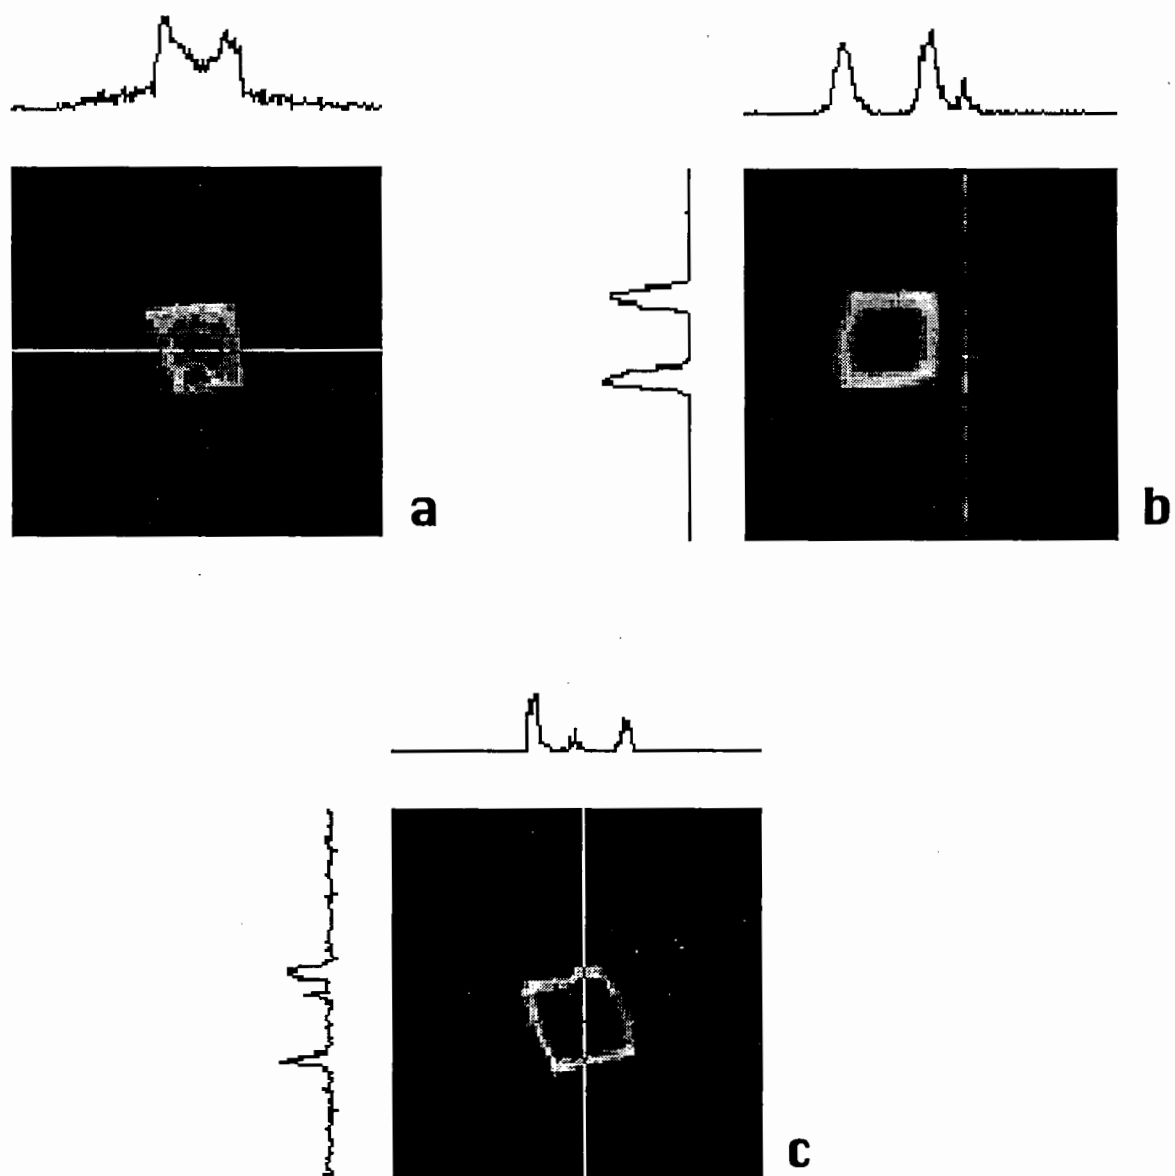

The Figure presents transient images together with one-dimensional projections for each of the three macromolecular systems. The first (a) illustrates the swelling behavior of isobutyl rubber in toluene. In the case of a rubbery material, the transport behavior is anticipated to be Fickian. Analysis of the dynamic behavior of the isobutyl rubber confirms this: during the swelling interval a steep solvent gradient observed in the frame rapidly evolves into a smooth and shallower gradient indicative of a transport mechanism which is essentially Fickian.

The second (b) illustrates the swelling behavior of PEMA in methanol. Clearly evident is a sharply defined solvent front which separates a swollen region from the glassy core. Swelling is essentially complete when the solvent fronts meet at the object center. In general, this behavior is typical of all polymers which pass through a glass to rubber transition during solvent uptake. The term case II has been used to describe such transport phenomena. Analysis of the transport of pyridine during the swelling of a sample of high volatile bituminous coal (c) clearly reveals a sharp concentration profile during the uptake process which is indicative of case II type transport behavior.

Data obtained from the imaging experiments has been used to construct a rigorous model governing case II transport. For solvent transport in a system undergoing a glass transition, we can define the uptake behavior using three parameters: a characteristic co-operative diffusion coefficient, governing dilation of the network; a molecular relaxation rate constant; and a critical solvent concentration above which there is a transformation of the network from a glass to a rubber.

Sincerely,

Subject:  $^{31}\text{P}$ - $^{19}\text{F}$  Rotational-Echo, Double-Resonance (REDOR) NMR

Dear Dr. Shapiro,

Rotational-Echo, Double-Resonance (REDOR) NMR has been a very useful technique for retrieving information on weak heteronuclear dipolar coupling in the presence of large chemical-shift anisotropies (1).  $^{13}\text{C}$ - $^{15}\text{N}$ ,  $^{13}\text{C}$ - $^{31}\text{P}$ , and  $^{13}\text{C}$ - $^{19}\text{F}$  REDOR NMR techniques have been developed and applied to the study of various biological systems and polymeric materials (2). Recently, we extended REDOR to  $^{31}\text{P}$ - $^{19}\text{F}$  spin pairs for proton-absent or proton-dilute inorganic systems. The advantages of  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR are that 1) both  $^{19}\text{F}$  and  $^{31}\text{P}$  have almost 100% natural abundance, so that specific isotopic labeling may not be needed, 2)  $^{19}\text{F}$  and  $^{31}\text{P}$  also have large gyromagnetic ratios, allowing a greater range of measurable distances, 3) the high natural abundance and large gyromagnetic ratios result in high NMR sensitivity, and 4) for proton-absent or proton-dilute inorganic systems,  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR can be performed on a routine two-channel NMR spectrometer.

We performed the  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR NMR experiments on a Bruker MSL-300 spectrometer with a  $^1\text{H}/^{19}\text{F}$  and multinuclear double-tuned probe made by Doty Scientific, Inc. Fluorapatite ( $\text{Ca}_5(\text{PO}_4)_3\text{F}$ , FAP) was used as a model sample for the experiments.

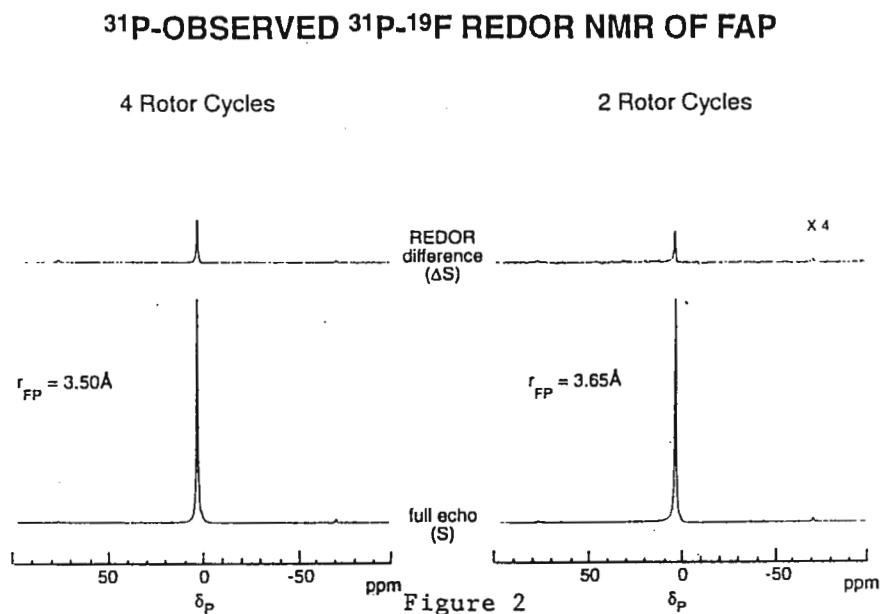

The  $^{19}\text{F}$ -observed  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR NMR spectra of FAP are shown in Figure 1a. After eight-rotor-cycle dephasing, the fluorine signal is almost completely dephased out. A strong difference signal is observed (Figure 1a, top). This result is expected since each  $^{19}\text{F}$  in FAP has three nearest  $^{31}\text{P}$  neighbors at a distance of 3.60 Å (3). The  $^{19}\text{F}$ -observed REDOR NMR spectra of  $\text{CaF}_2$  are shown in Figure 1b for comparison. Under the same experimental conditions, no F signal is dephased and the difference signal is null. The noise level in the difference spectrum

Procter &amp; Gamble

shows that REDOR could detect a difference signal as small as 0.3% relative to the full-echo signal.

It is not straightforward to determine the P-F distance by  $^{19}\text{F}$ -observed REDOR due to multiple- $^{31}\text{P}$  dephasing in this system. The P-F distance can be determined by  $^{31}\text{P}$ -observed  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR. Figure 2 shows the spectra of  $^{31}\text{P}$ -observed REDOR of FAP. The amount of dephasing is small after two- and four-rotor-cycle dephasing, and it is dominated by the nearest  $^{19}\text{F}$  neighbor. The experimental ratios of the REDOR difference signal to full echo signal,  $\Delta S/S$ , after two and four rotor-cycle dephasing, can be translated to a P-F distance of 3.65 Å and 3.50 Å (2) compared to 3.60 Å from X-ray data (3). This minor disparity is due to the additional dephasing by the three next nearest  $^{19}\text{F}$  neighbors, which are 4.9 Å away.

We have applied  $^{31}\text{P}$ - $^{19}\text{F}$  REDOR to studies of the interaction of ionic fluoride and hydroxyapatite, a primary inorganic constituent of dental enamel and dentine. The results are being submitted for publication.

Sincerely,

*Pan Yong*

# OVERSAMPLING AND DIGITAL FILTERING ON THE AVANCE™ DIGITAL SPECTROMETER SERIES

## DYNAMIC RANGE ENHANCEMENT

It is well known in fundamental signal processing theory that the ultimate dynamic range of an oversampled signal after digitization and data reduction by a modern Digital Signal Processor (DSP), is not only a function of the nominal dynamic range of the digitizer. At sampling rates greater than the Nyquist rate, the increase in dynamic range is equal to the square-root of the ratio of the sampling bandwidth ( $BW_{\text{samp}}$ ) divided by the effective spectral width ( $BW_{\text{eff}}$ ) after decimation.

$$\text{dynamic range increase} = \sqrt{BW_{\text{samp}}/BW_{\text{eff}}}$$

Figure 1 illustrates this point for the 16 bit 400 kHz digitizer of the AVANCE DMX in comparison to typical proton acquisition bandwidths. For instance, at its maximum sampling rate  $BW_{\text{samp}} = 200$  kHz, and for a typical 10 kHz proton spectral width, i.e.  $BW_{\text{eff}} = 10$  kHz, the increase in dynamic range is  $\sqrt{20} = 4.47 > 2$  bit. The total dynamic range of the oversampled and digitized signal after decimation and digital filtering by DSPs; is **greater than 18 bits**.

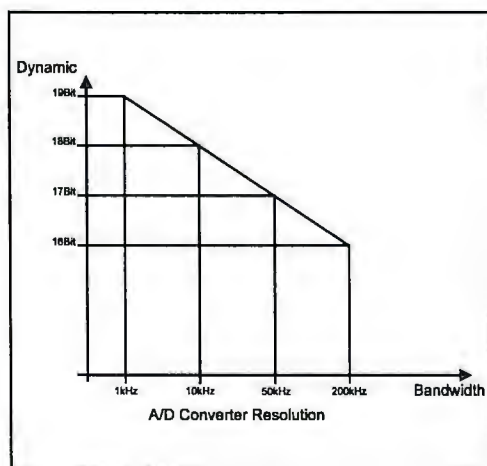

Figure 1: Dynamic range theory

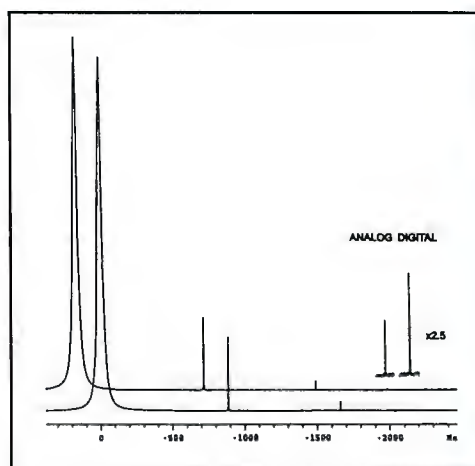

Figure 2: DMX600 dynamic range test

NTMR

Ultimately, NMR spectroscopists wish to see the "proof in the pudding", i.e. a high-dynamic range NMR experiment. For several years, Bruker has used a dynamic range sample with proton ratios of 10,000 : 100 : 10 : 1 to demonstrate the high dynamic range of the SE451™ receiver system, even without oversampling. Figure 2 shows this sample measured with a single scan with analog filtering, and with oversampling and digital filtering on an AVANCE DMX600. The smallest proton signal has been measured with the following signal-to-noise ratios:

Table 1:	Analog Filters	Oversampling & Digital Filters
S/N ratio:	80 : 1	200 : 1

The crucial point of this NMR test is that **under conditions of high dynamic range**, but otherwise identical experimental conditions, **oversampling and digital filtering on a DMX600 increase the dynamic range experimentally by a factor of 2.5.**

## SIGNAL-TO-NOISE IMPROVEMENT

Analog filters are characterized by relatively gradual filter cutoffs outside the passband. This causes both signals and noise outside the analog filter passband to be folded back into the spectral region. As a result, the signal-to-noise is highest near the center frequency and is lower near the edges due to noise which is folded back from outside the passband.

On the contrary, digital filters have extremely sharp cutoffs, and provide almost 100 dB attenuation, at the point where an analog filter has its 3 dB point. Therefore, aliased peaks are not a problem, and practically no noise is folded back into the spectrum from outside the passband. Therefore, S/N is approximately constant within an NMR spectrum when digital filters are used. This point is illustrated by the plot in Figure 3.

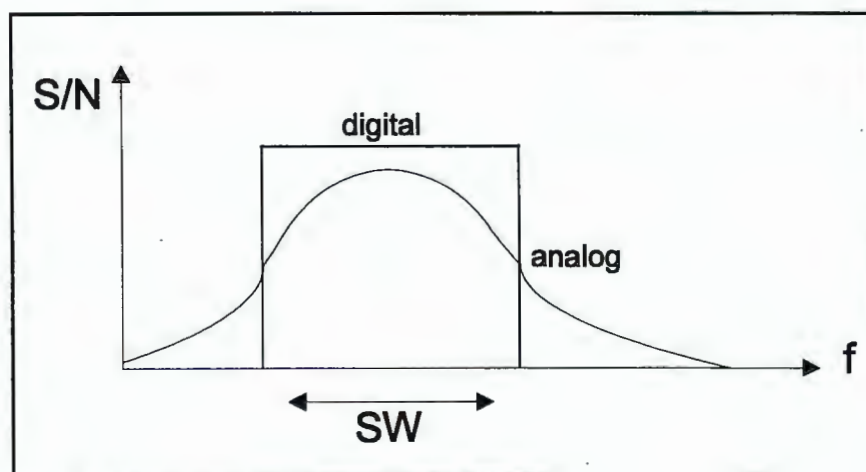

Figure 3: S/N comparison plot of analog and digital filters

It is clear that in the standard 0.1% ethylbenzene (EB) sensitivity tests used in NMR, the apparent signal-to-noise ratio increases significantly when only 200 Hz of noise are measured near the center of the EB spectrum. A more realistic test is shown in Figure 4, where the noise in EB is measured over a 2 ppm region from 4.8 to 6.8 ppm. At 600 MHz the spectral region for EB of approximately 8 ppm corresponds to a spectral width of only 5 kHz, and in an analog filtered EB test significant noise is folded in from outside the spectral region. With digital filtering on an AVANCE DMX600 no noise is folded back, and the sensitivity of the experiment is excellent: on a 5 mm proton selective probe the **measured S/N is greater than 900 : 1**.

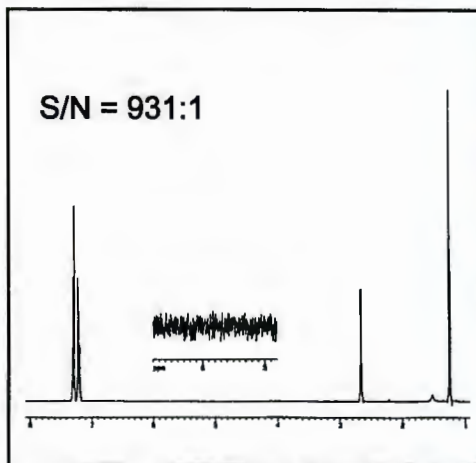

Figure 4: 0.1% ethylbenzene S/N test on DMX600 with digital filtering

Perhaps more interesting is a biological NMR experiment on lysozyme, where the signal-to-noise ratio is measured for the amide region near the edge of the spectrum. As illustrated in Figure 3, at the edge of the spectrum the sensitivity advantages of digital filtering should be even more significant. Indeed, Figure 5 demonstrates a **30% signal-to-noise improvement** specifically in the amide region when digital filtering is employed on a DMX600, compared to analog filters.

Similarly, a standard 2 mM sucrose sample exhibits a **signal-to-noise improvement of 25%** on the anomeric protons for digital filters compared to analog filters on an AVANCE DMX600 under otherwise identical conditions. This point is illustrated in Figure 6.

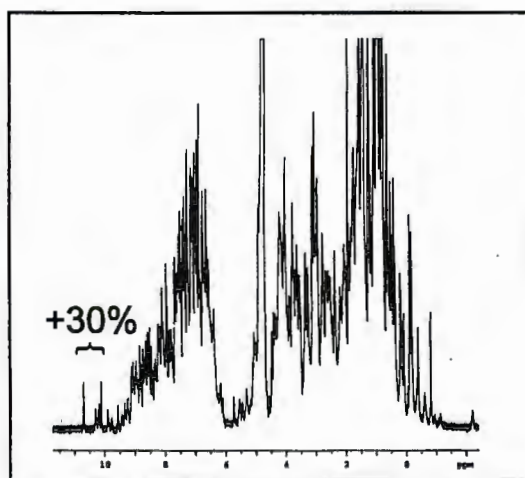

Figure 5: Lysozyme S/N with digital filtering

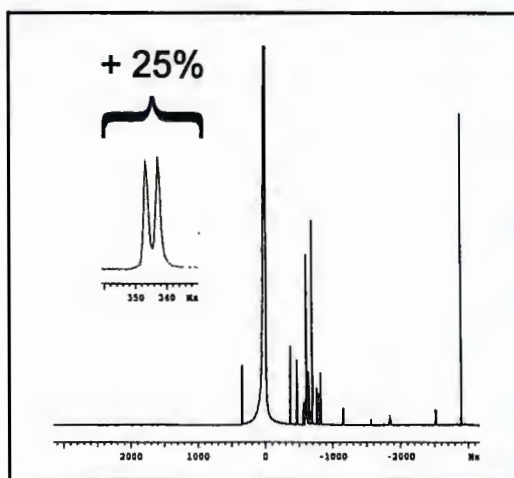

Figure 6: 2 mM sucrose S/N with digital filter

NMR

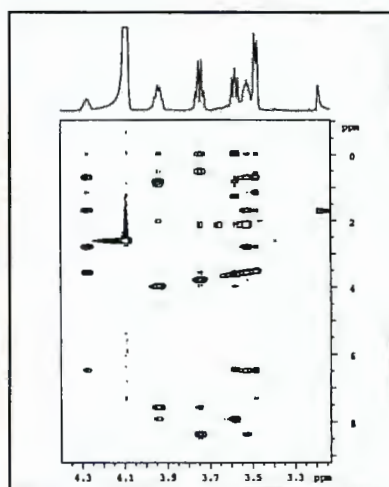

Figure 7a: Analog filters

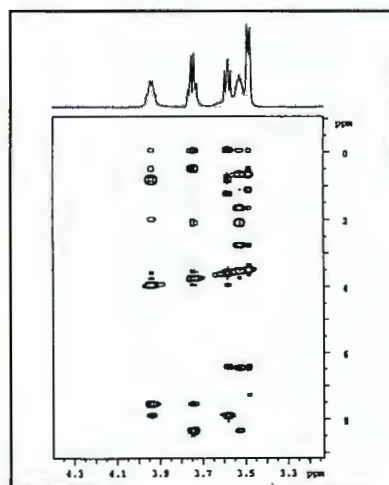

Figure 7b: Digital filters

## SHARP FILTER CUTOFFS OF FINGERPRINT REGIONS

Often it is desirable to measure only selected "fingerprint" regions in multidimensional NMR spectroscopy for optimal efficiency. Oversampling and digital filtering, due to the steep filter cut-off in the acquired dimension allow the acquisition of artifact-free fingerprint regions without concern about folded sample or solvent peaks.

In the example chosen here a small spectral region is selected from the 2D NOESY spectrum of gramicidine. In Figure 7a the region from 3.1 to 4.4 ppm is selected with analog filters, but folded peaks and artifacts make this approach unpractical. On the other hand, in Figure 7b the same region is shown, but in this case selected by digital filters on a DMX600. **The "fingerprint" region is free of artifacts and folded peaks when digital filtering is employed.**

Finally, the combination of shaped selective or band-selective pulses in F1 with oversampling and digital filtering in F2 is illustrated in Figure 8. Obviously, this combination permits spectral selectivity in several dimensions. It is expected that the **combination of shaped pulses with digital filtering** will be a powerful tool for carrying out efficient selective experiments of lower dimensionality which are equivalent in information content to higher-dimensional experiments without the need to acquire for long periods of time. For example, it is attractive to carry out a series of selective 2D (3D) experiments, to obtain structural information equivalent to 3D (4D) experiments, when the higher spectral dispersion over several dimensions is required only for certain cluttered regions with overlapping spectral features (as is often the case).

## Big Shakes and Big Cans

Dear Dr. Shapiro,

We recently finished installing our new Bruker AMX2-600 NMR spectrometer equipped with an Oxford magnet. During the installation of the magnet we devised a method for securing the system in case of earthquakes. In the past we secured magnets by bolting brackets to the floor which prevented the magnet stand from sliding or tipping over. The 600 MHz magnet, however, presented a couple of more problems. First, the magnet is not secured to its stand. This is especially dangerous since the vertical acceleration in an earthquake can exceed the acceleration of gravity, which would separate the magnet from its stand. Second, this magnet is substantially heavier and has a much higher center of gravity than those on our lower field instruments making the floor brackets alone ineffective. We decided the best method was to secure both the top and bottom of the magnet system. The top of the magnet was attached to the concrete walls and the steel girders above the magnet using 1/2" Dacron line obtained from our local boating store. The magnet stand was first secured to the magnet using anodized aluminum brackets made in our machine shop and then steel brackets were bolted to the floor to prevent the system from sliding during an earthquake. These brackets were carefully designed to not touch the stand so that the system remains isolated from the floor vibrations. We figure if these safety devices fail in an earthquake we will have many more things to worry about than the state of our NMR spectrometers (like the building falling down). If anyone would like details of how our magnet is secured please write to me or Mike Maddox.

Relaxation of quadrupolar nuclei in clusters.

Dear Bary,

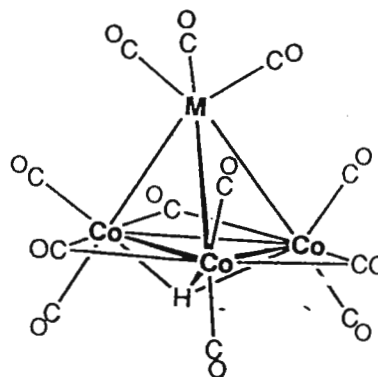

We have recently measured the relaxation time of cobalt on tetrahedral clusters (see figure below) in solution. The relaxation mechanism is largely quadrupolar and the experiments show a monoexponential behaviour which means that, according to Abragham, we are in the extreme narrowing case where the usual formulae apply.

On the other hand, we have all the electric and magnetic parameters from the solid state spectra (J. Hirschinger, P. Granger, J. Rosé, J. Phys. Chem., 1992, 96, 4815). If we accept that these parameters remain in solution, it is easy to deduce the correlation time of those species.

The table below shows that the result is surprisingly good for those molecules which have quite different relaxation times. The simple model of the sphere in a viscous liquid is a well suited model which gives a radii of gyration which agree with the molecular geometry. Other models does not fit so well. This type of rigid molecules, where the cobalt is not directly in contact with the solvent seems to be appropriate molecules for the theory of relaxation.

Best regards,

# Maximize Throughput with Varian's Sample Management System

## And Watch Your Productivity Soar

With the push of a button or a click of the mouse, Varian's Sample Management System (SMS) autosampler reliably delivers a sample to the magnet faster than any other system. Combined with a UNITYplus™ or Gemini spectrometer, this new-generation autosampler offers the highest throughput capability for automated NMR experiments.

The SMS autosampler uses state-of-the-art robotics for the fastest sample turnaround, continuous unattended operation, and long-term positional

accuracy. Self-calibration and a tactile-sensing gripper provide the most reliable sample handling, while a single user interface controls both the SMS autosampler and the spectrometer for easy operation.

Fully automatic data acquisition and processing software, combined with Varian's Auto•nmr probes and the SMS autosampler, deliver unparalleled automation for your demanding workload. Call your local Varian representative for details today.

### Color Figures for Sun/SGI.

Dear Barry:

There has been a fair amount of discussion in the Newsletter about how to get publication quality figures. Black and white figures are necessary, but it would also be nice to get high resolution color figures. We have used two handy tools for this purpose. On our SGI boxes running Felix, we have used the Irix tool "snapshot." A more powerful tool is "xv" which runs on both Suns and SGIs. We use xv to capture an image of a color 2D contour plot for example. We write out the image in SGI format, even on the Sun, and then convert it to PICT format with the the "topict" tool in the SGI 4Dgifts directory, or the "imconv" tool available from the San Diego Supercomputer Center. The PICT file can then be transferred to your favorite Macintosh. We have been using MacDraw Pro to dress up the images and then make color slides using a LaserGraphics slidemaker.

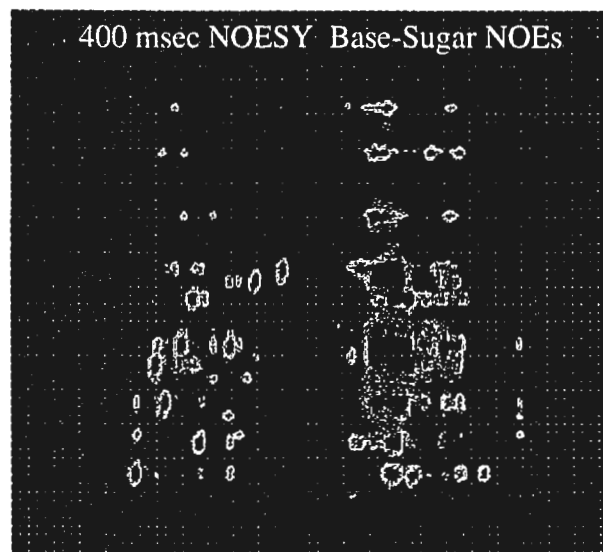

I have made the binaries for xv\_sun and xv\_sgi as well as the man page available for anonymous ftp from adenosine.pharm.utah.edu. Sources that go right up on the SGI can be found on jhunix.hcf.jhu.edu in the directory public\_domain\_software/SGI/xv. An email address for SDSC is consult@y1.sdsc.edu.

The figure has been converted to black and white, but on the slide is glorious color straight from a Sparc1 running VNMR.

Title: A  $^{113}\text{Cd}$  NMR Study on an Alkylamino Sugar

Dear Dr. Shapiro,

As part of our research program, studying the conversion of carbohydrates, a number of amino sugar compounds with potential as metal sequestering ligand properties have been synthesized.  $^{113}\text{Cd}$  NMR is a valuable tool to study the coordination of these ligands.

We observed  $^{113}\text{Cd}$  resonances for complexes of N-donor ligand L in aqueous solution at ambient temperature.

L:

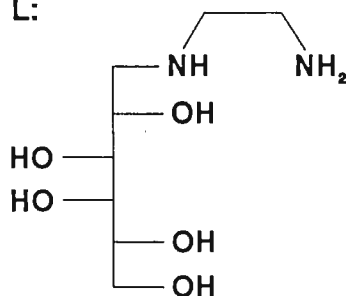

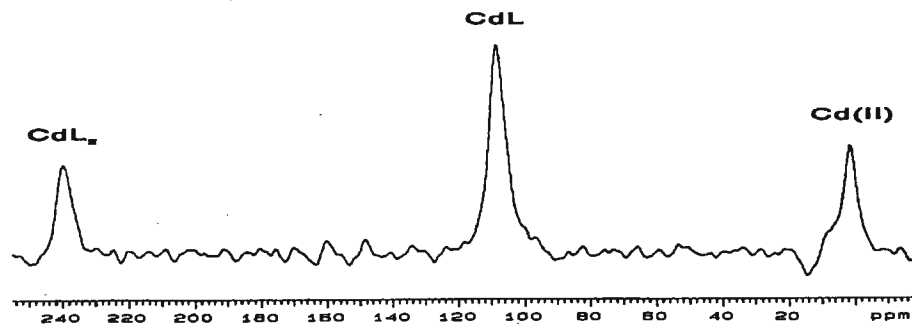

Figure 1 shows the  $^{113}\text{Cd}$  NMR spectrum at  $(\text{Cd(II)}/\text{L})$  molar ratio ( $\rho$ ) 1 at pH 7.5. At  $\rho = 1$  free  $\text{Cd(II)}$  (0 ppm),  $\text{CdL}$  (108 ppm), and  $\text{CdL}_2$  (239 ppm) give distinct resonances indicating these species to be in slow exchange.

The  $^{113}\text{Cd}$  NMR spectra carried out at pH 12 at several  $\rho$  values show the presence of  $\text{CdL}_2$  (228 ppm) and  $\text{CdL}_3$  (276 ppm). Comparison of these chemical shifts with literature values suggests that both N-atoms of the ligand L are coordinated with  $\text{Cd(II)}$  in these species. Current research is being carried out to investigate the existence of additional coordination between one of the OH groups in the carbohydrate chain and  $\text{Cd(II)}$ .

Dear Barry:

**Application of the Simultaneous Determination of Magnesium and pH  
from the  $^{31}\text{P}$  Shifts of ATP**

Evidence that the intracellular concentration of free magnesium ion  $[\text{Mg}_f]$  may serve a regulatory function has renewed interest in its quantitation. In our studies, we prepared model calibration solutions as a function of total  $[\text{Mg}]/[\text{ATP}]$  and pH and numerically modelled the three  $^{31}\text{P}$  NMR chemical shift differences of ATP ( $\delta(\gamma-\alpha)$ ,  $\delta(\alpha-\beta)$  and  $\delta(\gamma-\beta)$ ) (1). We also used these calibration surfaces to obtain improved shift limits. This is necessary for the standard  $[\text{Mg}_f]$  method of quantitation which assumes fast exchange and a single apparent  $K_D$  for MgATP.

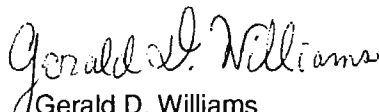

We now present a high field (9.4 T) *in vivo* demonstration of our 2-dimensional calibration methods for determining magnesium ion concentration  $[\text{Mg}]$  under conditions of fluctuating pH. The effect of 3 h of hypoxic-ischemic (HI) insult on intracellular brain  $[\text{Mg}]$  was evaluated using a well established 7-day-old rat model of cerebral HI (2). During the final hour of HI there was a significant increase in free magnesium as well as in the ratio of total  $[\text{Mg}]/[\text{ATP}]$ . The normal, HI, and early recovery (1-2 h) values of free  $[\text{Mg}]$  were  $0.336 \pm 0.015$ ,  $0.501 \pm 0.104$  and  $0.326 \pm 0.08$  respectively. These results are consistent with the temporal decrease in  $[\text{ATP}]$  during hypoxia and its return toward the normal neonatal value of 2.8 mM during recovery. Despite numerous papers which claim changes in  $[\text{Mg}]$  with altered physiological state, little attention has been paid to the uncertainty in the final result. Figure 1 shows a graphical representation of the uncertainty in either  $[\text{Mg}_f]$  or  $[\text{Mg}_T]/[\text{ATP}_T]$  for an uncertainty in both chemical shift difference and pH. The small uncertainty in  $\delta(\alpha-\beta)$  for normal brain was obtained by averaging of numerous controlled measurements. With consideration of  $\delta(\gamma-\alpha)$ , the error in the pH of the ATP compartment may also be calculated. This evaluation of ATP shifts is general for most *in vivo* applications and will favor lower  $[\text{Mg}_f]$  values than most prior estimates.

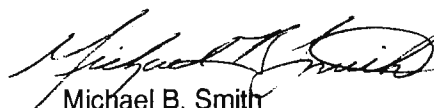

A software package, denoted as *MAGPAC* (MAGnesium and PH from ATP Calculation), has been written to perform all of the necessary calculations and uncertainty plots from the input  $^{31}\text{P}$  NMR shifts. A user friendly IBM PC version of *MAGPAC* is available and can be accessed by ftp to anonymous@psunmr.nmr.hmc.psu.edu in the pub directory.

**Figure 1:**  $[Mg]$  (upper plot) and  $[Mg]/[ATP]$  (lower plot) error representation due to chemical shift and pH uncertainties. The shaded regions bracket the standard deviation in chemical shift, while the dashed lines locate the uncertainty in  $[Mg]$  for the estimate of the uncertainty in pH. Normal 7-day-old rat brain  $[Mg]$  (lower shaded region of each plot) is compared with the values at 2-3 h of hypoxic-ischemic insult (upper shaded region of each plot). A pooled t-test of the final results support a significant difference in  $[Mg]$  for the two populations ( $P < 0.0001$ ).

Answer Back Code: OSU CHEM UD

The Shared Analytical Instrument Laboratory in the Department of Chemistry at The Ohio State University has a position open for a NMR spectroscopist at the Senior Research Associate level. Candidates must have a doctoral degree in chemistry, or an equivalent combination of education and experience, and extensive experience in physical science research involving the application of FT-NMR to chemical problems. The NMR Laboratory Manager is responsible for the operation and scheduling of the four NMR spectrometers in the facility, for instructing students in NMR operation and for managing the business affairs of the NMR facility. The optimal candidate would have experience in the hardware and software associated with modern NMR spectroscopy and would be interested in performing collaborative research with faculty members. Experience with Bruker AC-250 and AM-300 NMR instruments is highly desirable. Send resume and three letters of recommendation to Dr. Dale H. Karweik, The Ohio State University, Department of Chemistry, 120 West Eighteenth Avenue, Columbus, OH 43210. The review of completed applications will begin January 1, 1994 and applications will be accepted until the position is filled. The Ohio State University is an Equal Opportunity/Affirmative Action Employer. Women, minorities, Vietnam-era veterans, disabled veterans, and individuals with disabilities are encouraged to apply.

# Almost Every NMR and MRI Test Depends On This Moveable Part

... and **Voltronics** makes most of them. By working closely with this community of researchers and engineers for 26 years, we offer you a broad line of the latest non-magnetic precision trimmer capacitors.

## Features:

- Truly non-magnetic. Distortion of magnetic field below one part per 600 million.
- Long life, non-rotating piston design.
- O-ring seal.
- Linear tuning with positive stops.
- Tuning screw does not go in and out, allowing extended shaft option.
- High Q to over 5 GHz on some parts.
- Quartz, glass, sapphire, Teflon® and air dielectrics.

## Standard Line:

Over 144 catalog parts including:

- Max. capacitance from 3.5 to 120 pF.
- Peak RF voltage to 15KV.
- Greatly expanded Teflon Line.
- A .48" (12.2mm) x .23" (5.8mm) diameter 9pF Teflon trimmer with 1.5KV peak RF voltage.

## Custom Design

- We'll be glad to modify a standard part or design a new one for you.

## Special Designs

- Dual trimmers — Differential and Split Stator.
- Antennas and coils fused to quartz or glass tubes.
- Non-magnetic slip clutch to protect capacitor stops.

## New Catalog

- Our new catalog lists many non-magnetic and standard parts. It includes data on RF peak voltage ratings and high frequency Q measurements.

For further information and our new catalog, call, fax, or write Voltronics or your local representative.

## **TAMU NMR Newsletter - Book Reviews**

Book Review Editor: **William B. Smith**, Texas Christian University, Fort Worth, TX 76129

### **" A Dictionary of Concepts in NMR "**

by

**S.W. Homans**

Oxford University Press, Walton Street, Oxford OX2 6DP;  
revised, paperback edition; 1992; ISBN 0-19-854765-X \$29.95, 373 pages.

My first reaction on inspecting this new edition of "A Dictionary of Concepts in NMR" was that this must largely duplicate "A Handbook of Nuclear Magnetic Resonance" by Ray Freeman. But I quickly discovered that this was not so. The author claims that "the aim of this work is to aid chemists and biochemists familiar with the basic principles of NMR to understand the bewildering array of acronyms and technical jargon which is to be found in the literature." I think he has succeeded admirably. While there are the inevitable overlaps with portions of the Freeman book, they actually complement each other quite nicely, and I am glad to have both of them on my bookshelf.

The single most obvious difference (other than the lack of cartoons) is the inclusion of a considerable amount of mathematical background. The point is made by citing four appendices titled as follows: Properties of cartesian product operation; Trigonometric identities; Matrix algebra; and Rotation operators. No one would pretend that these are detailed treatments, but they do get your feet wet if you willing to wade in.

Many entries are accompanied by references for further reading.

W. B. S.

## Advanced Clinical MRI/MRS and $^{13}\text{C}$ MR Spectroscopy

Continuing Education Course at UT Southwestern Medical Center at Dallas

**Thursday, March 10, 1994**

**PROGRAM DIRECTORS:** Craig R. Malloy, M.D., and A. Dean Sherry, Ph.D.

**PROGRAM COORDINATORS:** Navin Bansal, Ph.D., and Evelyn Babcock, Ph.D.

**COURSE OBJECTIVE:** This one day program is aimed at physicians, biomedical scientists and graduate students who are interested in the application of magnetic resonance spectroscopy and imaging to physiology. In the morning session, the role of NMR methods in the investigation of brain, heart and skeletal muscle physiology, and breast imaging will be discussed by experts in the field. In the afternoon session, an overview of current  $^{13}\text{C}$  NMR spectroscopy methods for analysis of intermediary metabolism will be presented.

This symposium will be held the day following the first annual meeting of the Society of Magnetic Resonance (SMR).

**GUEST SPEAKERS:** J. J. H. Ackerman (Washington U), Jeffry R. Alger (NIH), Steven Harms (Radiology Associates of Dallas), Douglas Rothman (Yale), Heinrich Taegtmeyer (UT, Houston), Robert G. Weiss (Johns Hopkins).

**UT SOUTHWESTERN SPEAKERS:** James Fleckenstein, Ronald Haller, Mark Jeffrey, Craig R. Malloy.

**For more information, call:** Dolly Christensen at (214) 648-8013 or Navin Bansal at (214) 648-5887.

### Monitoring of Probe Heat Dissipation

Dear Barry:

Recently, we were interested in determining the heat dissipation performance of our inverse probe in the context of a heteronuclear experiment with  $^{13}\text{C}$  decoupling. The experiment was performed by recording  $^{13}\text{C}$  sidebands of a mixture of 20%  $\text{CH}_3\text{OH}$  ( $^{13}\text{C}$  natural abundance) / 80%  $\text{CDCl}_3$  with centerband suppression by a difference experiment. As shown in Figure 1, the pulse sequence included  $^{13}\text{C}$  off-resonance CW irradiation with a defined duty cycle and sufficient power to see the temperature rise at the start of the experiment. For our mixture, the chemical shift temperature coefficient for the OH peak was 0.016 ppm/K. Therefore, it was expected that a temperature fluctuation during the difference experiment would result into a large residual OH peak.

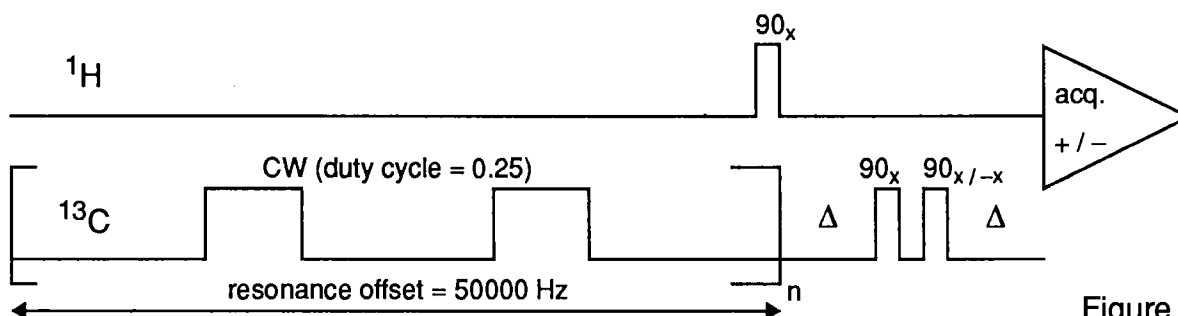

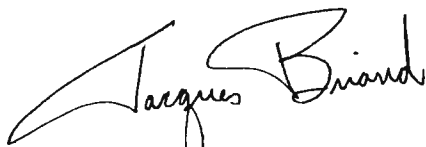

Figure 1

Two series of 64 difference experiments were performed, one for a duty cycle = 0, and the other for a duty cycle = 0.25. The former served as a reference for the steady-state intensities (magnitude mode) of the residual OH peak, the residual centerband and the two  $^{13}\text{C}$  satellites (Figure 2). The CW pulse had a length of 16 seconds, a field strength of 3.5 KHz and a resonance offset of 50 KHz, sufficient to not disturb the  $^{13}\text{C}$  resonance of interest. With the residual OH peak intensity, it is possible to evaluate the time it takes to reach a steady-state temperature. For a duty cycle of 0.25 it can clearly be observed that the temperature takes about 10 minutes to reach a steady-state value. The intensities were normalized with respect to the intensities of the  $^{13}\text{C}$  satellites.

This experiment does not yield any quantitative information about the temperature inside the sample. However, it is useful for measuring the time a probe takes to reach a steady-

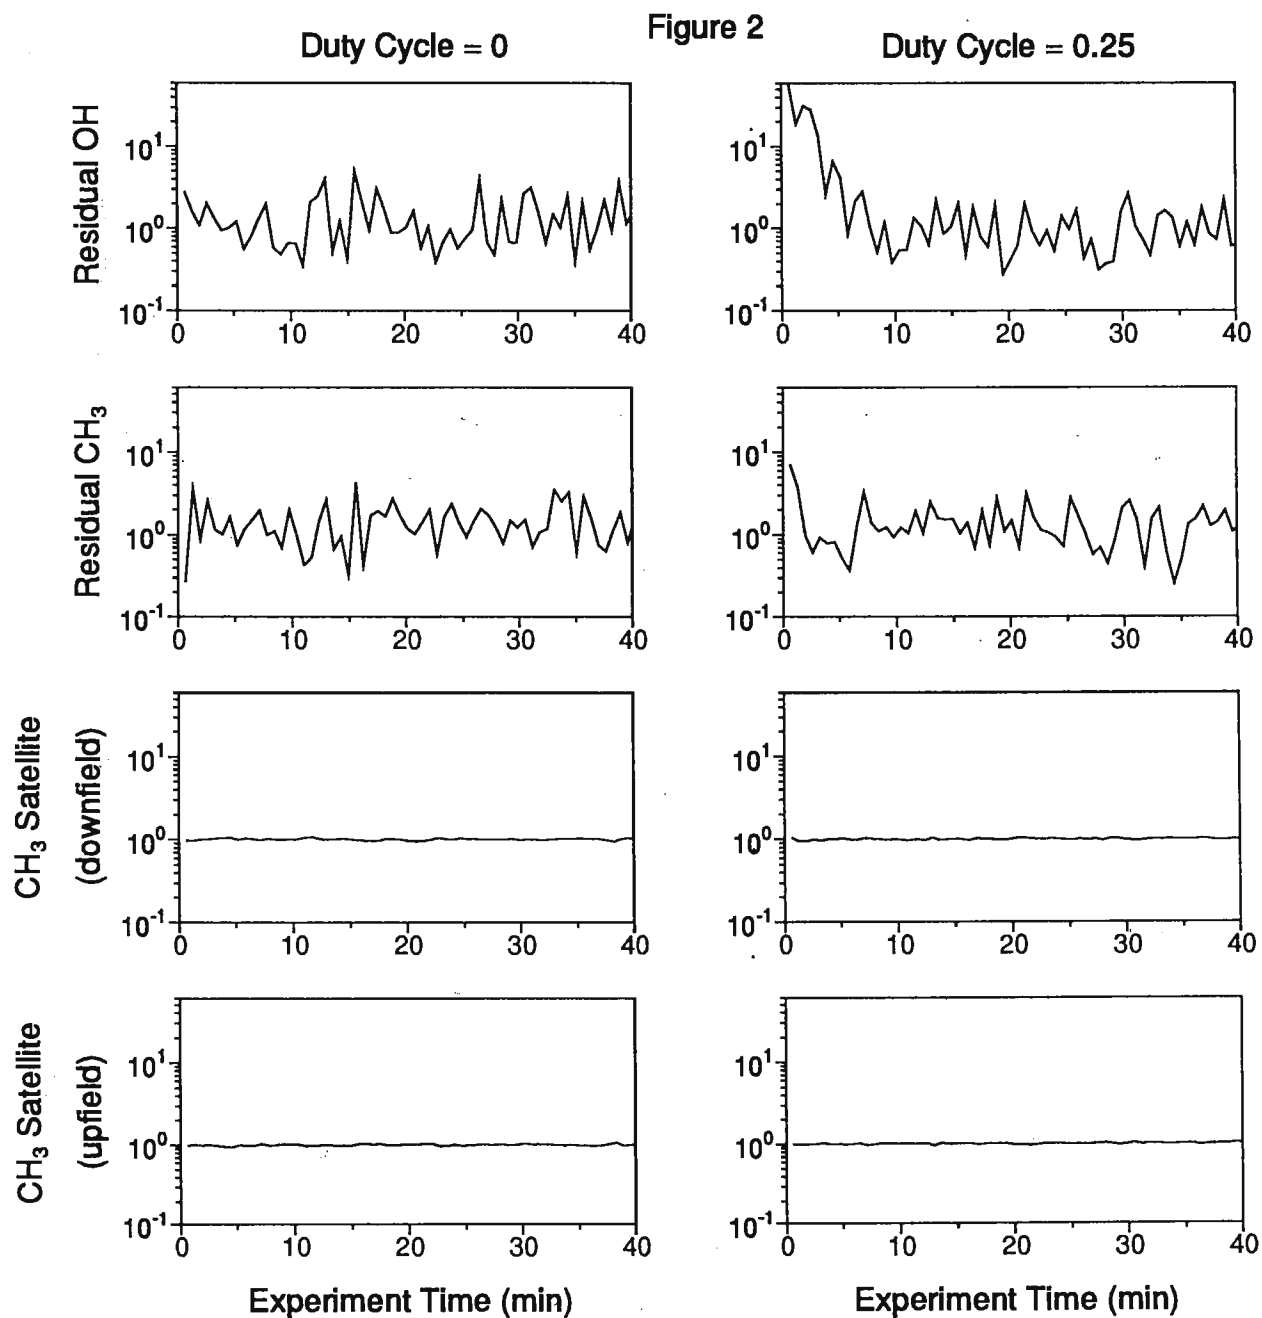

state temperature, assuming the experiment being performed is fairly periodic.

Sincerely yours,

Jacques Briand

## 2D INVERSE LONG-RANGE C-H-SHIFT CORRELATION

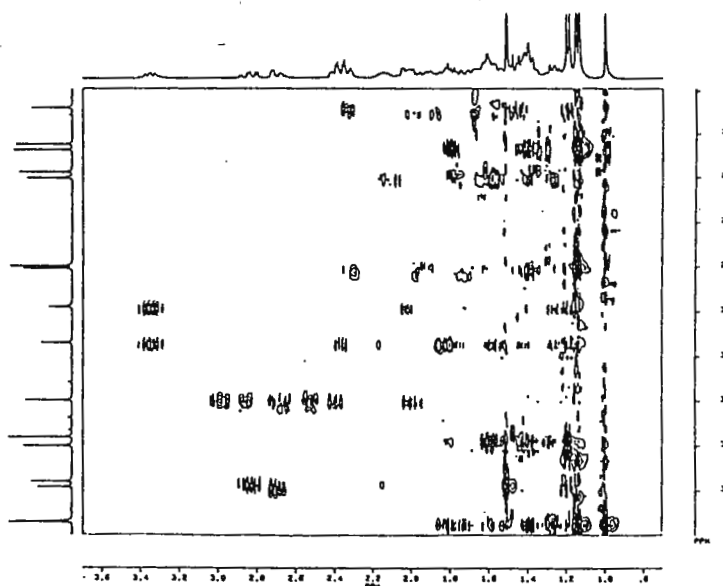

Dear Dr. Shapiro

Unsatisfied with the spectral quality achieved with the HMBC-Experiment to selectively detect and measure carbon-proton long-range coupling interactions which is probably caused by the instabilities of our BRUKER AM-400 system, we tried out the subsequent inverse experiment, which starts with (NOE enhanced) carbon z-magnetizations and which transfers the carbon-shift modulated carbon coherences to proton antiphase coherences in the final step immediately before detection. We were astonished about the high quality of the corresponding spectra, especially with respect to the suppression of unwanted C-12 proton signals. The reason for this are the three purge pulses, two of them applied as a "sandwich" with x- and y-phase respectively at the beginning and a third one immediately before acquisition. Together with the CPD decoupling at the beginning they are responsible for the highly efficient saturation of all proton signals and the high quality even with the rather short phase cycle (see below):
